

ABSTRACT

There is provided a PC steel member fixing wedge, in which split pieces can be equally arranged around the PC steel member so as to prevent any deviation of a stress to be applied to the PC steel member.

The PC steel member fixing wedge is formed into a conical shape by combining a plurality of split pieces 11 with each other and grasps the PC steel member. A restraint ring 20 is provided for holding the split pieces 11 in the conical shape. The restraint ring 20 has a projection 21 to be fitted into a clearance defined between the split pieces. The projection 21 formed at the restraint ring 20 is configured in such a manner as to be fitted into the clearance defined between the split pieces 11, thus equally holding the arrangement of the split pieces 11 during the application of tension to the PC steel member and enabling the stress to be uniformly applied to the PC steel member.
